Clinical review

Hi Geoff,

Thank you for taking the first step towards a testosterone deficiency diagnosis.

Low testosterone could indicate testosterone deficiency and therefore you may benefit from treatment. Symptoms include low libido, erectile dysfunction, low mood, and weight gain. This will be discussed further during your consultation with the doctor.

Several of your results are within the healthy range. This indicates that aspects of your health are in line with recommended levels.

However, a few of your results are outside of the expected normal range: **Triglycerides, LDL, HDL, Non HDL Cholesterol, HbA1c, Estradiol, FSH, Urea, MCHC and Systolic Blood Pressure**. While some variations can be attributed to various factors like diet, stress, and daily activities, it's important to address any significant deviations from the norm.

In light of these findings, here are some insights and recommended steps:

- ◆ Some of your red blood cell markers are outside the usual range. Please discuss these with your GP who knows your medical history and can advise on any further steps.
- ◆ Your triglyceride and LDL levels are above the recommended range. Maintaining balanced levels is crucial for preventing cardiovascular issues and promoting overall health. While there can be various reasons for elevated levels, factors such as an inactive lifestyle or an unhealthy diet can contribute. To address this, consider minimising processed food consumption and incorporating regular exercise into your routine.
- ◆ Your urea is above the normal range. This is most likely due to dehydration, as your other kidney tests are within range. Most adults need to drink about 2 litres of fluid daily. Consider retesting your urea in 2 weeks.
- ◆ At your recent appointment, your blood pressure reading was 146 / 87 mmHg, which is considered high. This can cause symptoms such as headaches, blurred vision, chest pain and

dizziness. Common causes may include stress, lack of physical activity, an unhealthy diet (particularly high in salt), being overweight or obese, excessive alcohol consumption, smoking, and a family history of hypertension. Certain medical conditions such as kidney disease, diabetes, and sleep apnoea can also contribute to high blood pressure. It's important to follow up with your GP for further assessment and management. If you are currently experiencing any of the symptoms mentioned, please call 111 for advice.

- ◆ Your PSA reading is within the age-specific normal range. It is important to note that this does not take into account your medical history. If you have any concerns or your PSA has risen, we recommend that you speak to your GP who may order further investigations
- ◆ Non-HDL cholesterol, which encompasses all 'bad' cholesterol types, is linked to an increased risk of heart disease due to potential artery plaque buildup. Managing its levels is key for heart health and involves dietary, exercise, and possibly medical interventions.
- ◆ Your HbA1c is above the normal range and falls within the prediabetic range, indicating that you have too much glucose in your blood and are at an increased risk of developing diabetes in the future. It is important to book a routine GP appointment to discuss diabetes prevention and explore healthier lifestyle support services available in your area.
- ◆ Your HDL level is below the normal range, which is concerning since higher HDL levels are protective against heart disease. Foods like olive oil, fatty fish, nuts, and whole grains can help increase HDL levels.

We always advocate for proactive health management. Please consider these recommendations seriously and take the necessary actions. If you have any questions or concerns, don't hesitate to reach out to us.

If you suspect that you may be ill, or if you have any concerns about your blood results, please contact your GP as soon as possible for a full medical evaluation. These results are here to help you understand your health and not to constitute a clinical diagnosis.
